Abstract

In this study, the relations among 8 coping strategies were examined. A meta-analysis of 10 studies reporting a relation between problem-focused coping and emotion-focused coping was performed through the structural equation modeling approach. The problem-focused coping and emotion-focused coping correlation was significant. The overall intercorrelations among the subscales of the emotion-focused coping are weak in general. The advantages and limitations of the EQS program were also evaluated. The results have important implications for future research.
